`s.split  delimiter`

s0 split

`s1 split '-'`

Aim: How do split and join work?

```
split
```

   String method that creates a list from a string based on a delimiter (common substring that can be used to separate a string into smaller parts).

   The delimiter is not included in the list.

   The default delimiter is any whitespace. This includes newlines and tabs.

   syntax

```
   s.split( delimiter )
```

   Examples

```
   s0 = 'i love computer science!'
      s0.split() ==> ['i', 'love', 'computer', 'science!']

   s1 = 'john-paul-george-ringo'
      s1.split('-') ==> ['john', 'paul', 'george', 'ringo']
```
